Experiment:- 14

Problem statement:-

Linux provides powerful utilities to monitor user activity, manage files, and control process execution priorities. System administrators and cyber security professionals often need to determine how many users are currently logged in, list files in structured formats, and manage jobs running in foreground or background with controlled priorities.

The problem is to write shell scripts that display the number of users logged into the system, list files in a columnar format, and manage job execution using priority and background execution, thereby demonstrating system monitoring and job control through Bash scripting.

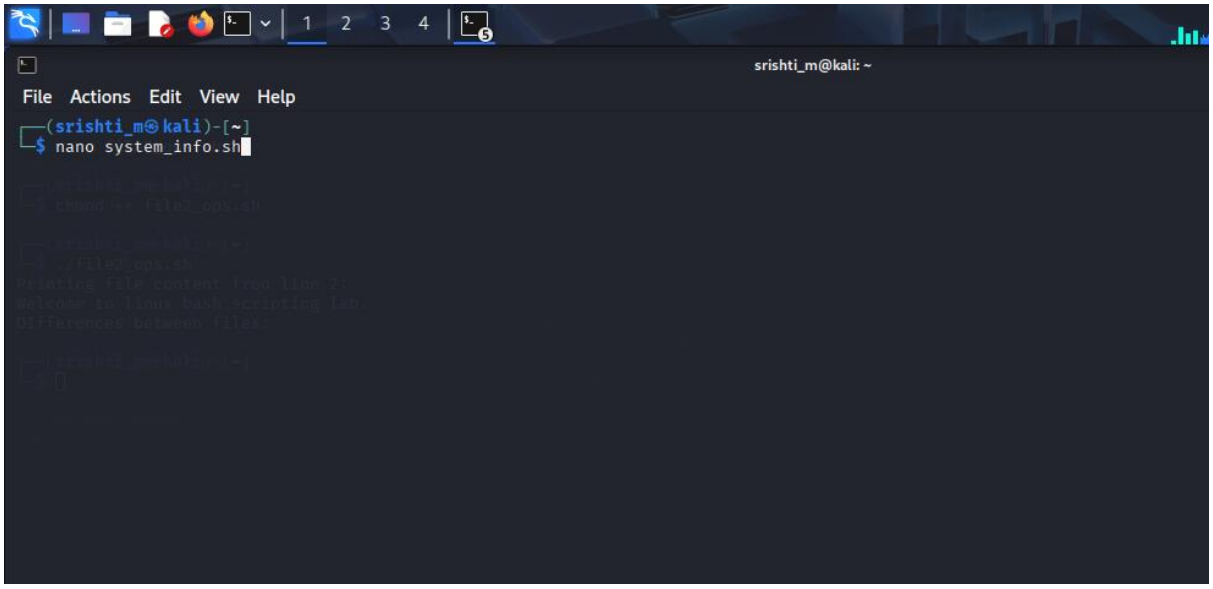
Aim:- Shell script for user login count, file listing and job control.

Procedure:-

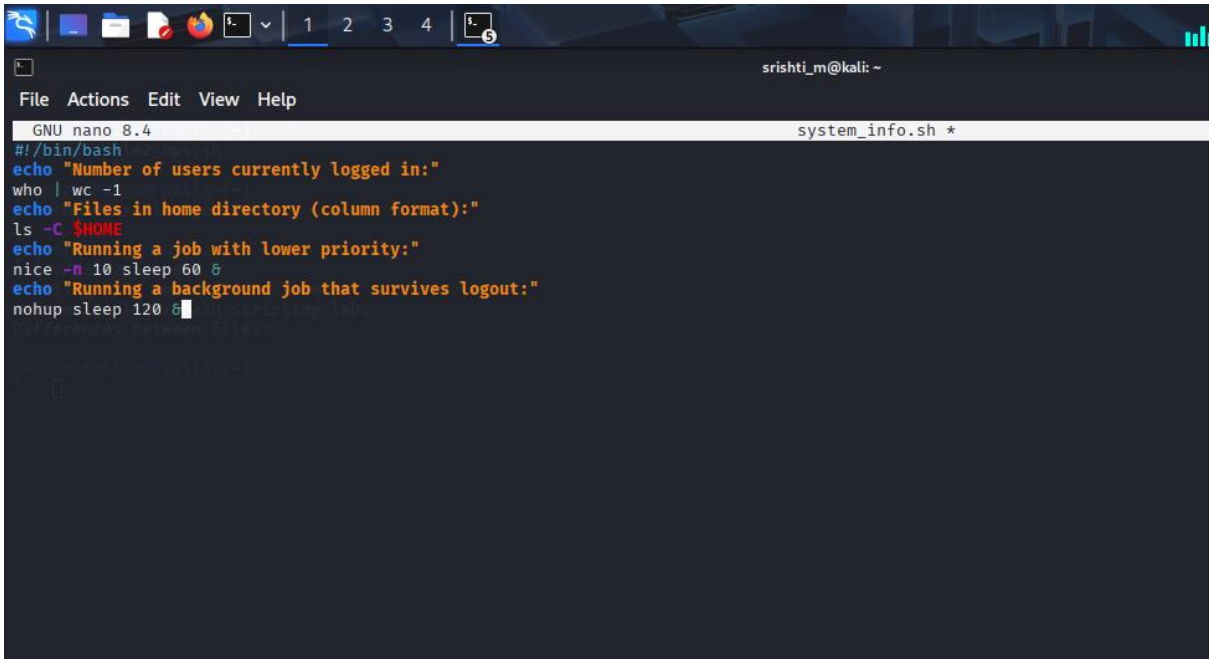
A. Writing the Shell Script

1. Open the terminal.

2. Create a script file: nano system_info.sh

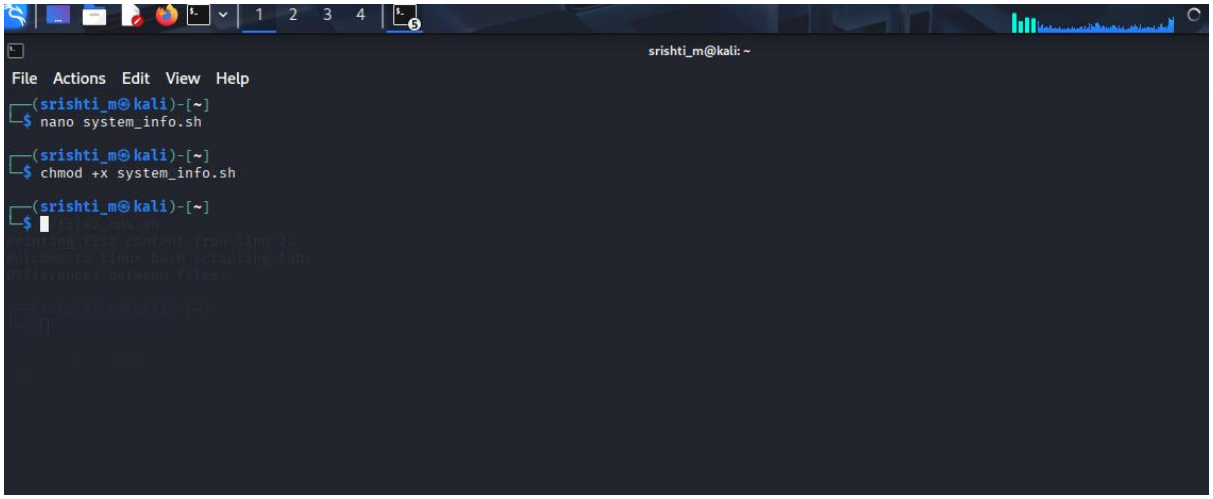


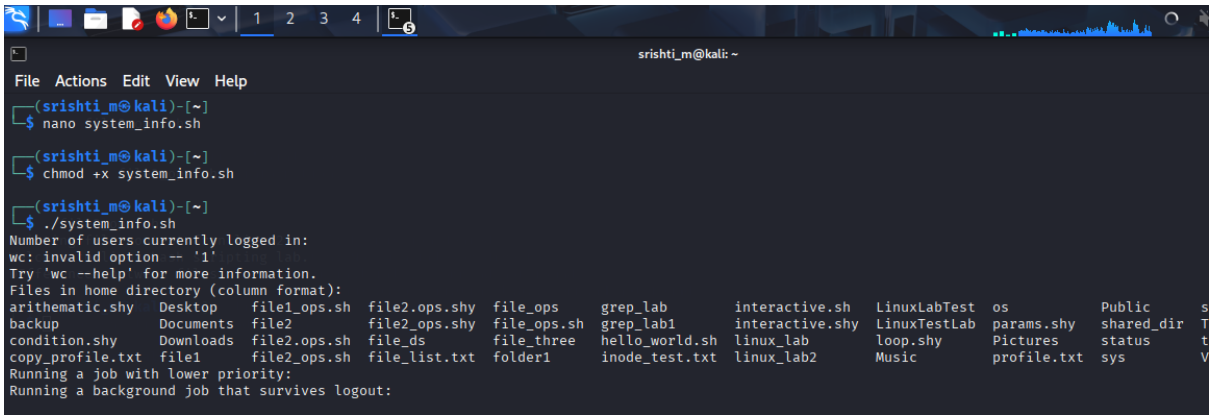
3.Enter the script:



4. Save and exit the editor.

5. Make the script executable: chmod +x system_info.sh



B. Executing the Script


6. Run the script: ./system_info.sh
